SUMMARY
Lead in drinking water was determined for all water outlets (n = 28) at Shoreham Elementary School (SES) in Shoreham, VT. Samples were collected according to the U.S. Environmental Protection Agency (EPA) guidance document 3Ts for Reducing Lead in Drinking Water in Schools. First draw (FD) and flush (FL) samples were collected, acidified (pH<2), and turbidity verified to be <1 NTU prior to Pb determination. Lead concentrations in FD samples were evaluated relative to two voluntary standards: the administrative (not health-based) 15-ppb EPA action level for residential water and the health-based 1-ppb American Academy of Pediatrics (AAP) safety recommendation for drinking fountains in schools. FL samples were used to determine the likely source of any lead in the water.

Most of the 28 outlets sampled (75%) produced FD samples that were at 1 ppb or lower and, therefore, meet the AAP recommended safety level. No samples exceeded the EPA action level. Seven sinks produced FD samples at 2 ppb or higher (range 2-14 ppb), exceeding the AAP recommendation. These sinks included two kitchen sinks/sprayers, four classroom or office sinks, and one utility sink. FL samples suggest that the source of lead is overwhelmingly the fixtures or their immediate connections and not more distal pipes or the incoming water supply, which simplifies potential remediation approaches.

The two kitchen sinks/sprayers were categorized as a highest priority for remediation because of their likely use for consumption and/or food preparation. The classroom or office sinks were categorized as high priority due to their potential use for direct consumption. The utility sink, located in a custodial closet, was categorized as a low priority for remediation because it is highly unlikely to be used for consumption.

Recommended permanent remedial actions include replacing fixtures with “lead-free” fixtures/solder with follow-up testing to verify remediation efficacy or removing priority outlets entirely. Additionally, we recommend that SES communicate the findings of this work and remediation updates with the school community, as well as post this report and remediation updates in a readily accessible location (e.g., school website). A sample letter describing the results for a general audience is provided.
Lead Levels in Drinking Water at Shoreham Elementary School, Shoreham, VT

Molly Costanza-Robinson, Ph.D* and Jennifer Ortega
Dept. of Chemistry & Biochemistry; Program for Environmental Studies, Middlebury College, Middlebury, VT. *Prof. of Environ. Chemistry, mcostanz@middlebury.edu
July 7, 2018

BACKGROUND

Lead exposures derive from a variety of sources including dust from older lead-based paint, soil contamination from earlier leaded gasoline, and water contamination from leaded pipes, solder, and fixtures [1]. Dust from leaded paint is believed to be the dominant source of lead exposure, but the EPA estimates that ~20% of lead exposure is through drinking water [2]. Health effects of lead include irreversible developmental neurotoxicity [3], disruption of the endocrine and reproductive systems [4], and gastrointestinal and cardiovascular issues [5]. Even at low levels (<5 μg-Pb/dL-blood), lead has been known to decrease IQ scores [3]. Because of the health risks posed by lead, including that it can bioaccumulate, the U.S. Environmental Protection agency has set a non-enforceable health standard (Maximum Contaminant Level Goal, MLCG) for lead in drinking water of zero [2]. While no level of lead exposure is considered to be safe for anyone, lead exposure is a particular concern in children. Whereas children absorb >50% of Pb that they ingest, adults absorb ~35-50% [6]. Furthermore, lead’s chemical similarity to calcium promotes uptake into children’s bones, which can leach out over time and serve as a long-term source of Pb exposure [7]. The American Academy of Pediatrics recommends a maximum lead level in drinking water of 1 μg/L (referred to as “ppb”) [8]. Because developing children spend much of their time at school and the effects are largely irreversible, exposure to lead through drinking water in schools is a critical issue [9, 10].

In 1991, the United States Environmental Protection Agency (EPA) established the Lead and Copper Rule, which requires public water suppliers to monitor for lead in drinking water and sets an action level for the concentration of lead in drinking water to 15 parts per billion (ppb) and a maximum contaminant level goal of 0 ppb [11]. If lead concentrations exceed the 15 ppb action level in more than 10% of customer taps sampled, public water suppliers must take action to control corrosion and inform the public about steps they should take to protect their health. Importantly, this action level is used administratively to evaluate community exposure and is not a health-based standard. The American Academy of Pediatrics has issued a health-based recommendation that water fountains in schools not deliver water exceeding 1 ppb lead [8]. Schools are not required to test for lead in drinking water unless they rely on a private water supply and serve more than 25 people daily [12]. This results in water being tested for lead in only ~8-11% of schools nationwide [13]. National legislative efforts, including those by former Vermont Senator Jim Jeffords, to direct the EPA to require states to develop school testing programs and to address any problems found have been unsuccessful. While municipal water must be tested for lead at the site of distribution and at a small number of end-user (typically residential) outlets, lead can leach into the water at various points within the system, including from lead-containing pipes, solder, and individual outlet fixtures. The federal 1986 Safe Drinking Water Act (in effect through 2014) limited the use of lead pipes and lead-containing solders in new drinking water systems, where “lead free” was defined as less than “0.2% lead for solders and fluxes and not more than 8% lead for pipes and pipe fittings” [14]. The amount of lead allowed in “lead-free” products installed after 2014 has been reduced, with the 2011 Reduction of Lead in Drinking Water Act redefining “lead free” as products in which wetted surfaces of a pipe contain a weighted average of ≤0.25% lead and the wetted surfaces of solder and flux contain a
weighted average of ≤0.2% lead. The 2011 revision also exempted from lead-free requirements certain products that are used exclusively for non-potable uses “such as irrigation, outdoor watering or any other uses where the water is not anticipated to be used for human consumption,” as well as other products, including shower or water distribution main gate valves ≥2 inches in diameter [14]. Because of shifting “lead free” definitions, exemptions from lead-free requirements, and uncertainty regarding individual pipe and fixture composition and installation dates, direct testing of water from each outlet is the only way to understand the potential for lead exposure through drinking water.

Data from the Vermont State Health Lab in 2015 indicate that ~5% of blood samples from Vermont children age 2-and-under exceed Vermont’s 5 µg/dL standard [15]. Approximately, 150 Vermont schools who are on their own drinking water supply regularly test some water outlets, but few schools have ever had all of their outlets tested. In 2017, the Vermont Department of Health and Agencies of Education and Natural Resources launched a pilot project to test all drinking water outlets in 16 Vermont public schools that are on municipal water supplies [16]. Results of that pilot showed substantial differences in the frequency of lead detection and in lead levels [17]. Schools ranged from having 0% up to 54% of outlets exceeding the EPA action level for lead, and from 3-88% of outlets exceeding AAP safety level of 1-ppb.1

Shoreham Elementary School (SES) receives water through Tri-Town water utility and, therefore, federal law does not require it to test for lead. The current study represents the first-time lead levels have been tested in water from all outlets at SES.

METHODS

Site Description

Shoreham Elementary School (SES) is located in the town of Shoreham, VT and serves ~75 kindergarten through 6th grade students each year [18]. SES is part of the Addison Central School District, which oversees public schools in the area. SES was constructed in 1960 with kitchen and current kindergarten classroom added later [19]. Much of the building was renovated ~10 years ago, and any new fixtures and solder were compliant with the lead-free requirements of the 1986 Safe Drinking Water Act. The kitchen sinks have aerators, but there is not a regular maintenance schedule for them. All outlets are flushed for 15 minutes at the start of the school year. We worked with ACSD Facilities Manager, Eric Warren, on the study design, including completion of a plumbing questionnaire and mapping of flow paths.2 All water outlets in the school that could potentially be used for consumption (n = 28), even if not intended for that purpose, were mapped by location and type. Outlets at SES included sinks (conventional and floor/utility), sprayers, bottle fillers (with chillers), and water fountains (with and without chillers) (Figure 1). Mapping included noting the flow path of water from the initial water entry point to the school. Knowledge of the water flow path is critical to the integrity of water sampling, as outlets need to be sampled in sequence from upstream to downstream to avoid inadvertent flushing of pipes and fixtures prior to sampling. We did not independently verify information provided regarding plumbing and water flow in the school. Prior to commencing sampling, ACSD Superintendent Dr. Peter Burrows agreed to share information about the water testing with the school community (Appendix A).

---

1 The AAP health-based recommendation is made specifically for water fountains, but would reasonably be applied to any outlet used for direct consumption by children. Information regarding use of outlets for consumption was not publicly available for statewide pilot.
2 EPA Plumbing Profile Questionnaire can be found on p 96 of (EPA 2006), and includes questions regarding pipe and fixture type and composition, building age, and dates of renovation, among other information.
Figure 1. Shoreham Elementary School floor plan showing water flow paths and water outlet (sample) locations. The location of water input to the school is in the marked with an X. Marker shapes indicate fixture type. The sample-naming scheme associated with outlets is provided in (Appendix B). The floor plan with outlet locations labeled by Outlet ID is provided in Appendix C.

Sample Collection

Water was sampled on two Saturday mornings (January 13 and 20, 2017) during the regular school year and prior to any use for the day.³ Water should ideally sit stagnant in the pipes and fixtures for least 8 h, but no more than 12 h before collection.⁴ Water samples were collected in certified clean HDPE Nalgene bottles (250 mL).⁵ Two types of samples were collected: first draw (FD) and flush samples (FL) (Table 1). The two types of samples collectively provide information on the source of lead in the water and therefore, on appropriate remediation measures. First draw (FD) samples were obtained by collecting the first 250 mL of water from each outlet. After all FD samples were collected, FL samples were obtained by flushing water out of the outlets for 30 seconds and then collecting another 250 mL. The outlets on the pink and yellow flow paths were sampled on a separate date from the outlets on other flow paths, due to uncertainty in the connectivity of the pink and yellow outlets and the desire to preserve sample integrity. Two field blanks were collected at Middlebury College the day before sample collection using ultra-purified water and were exposed to the sampling conditions of the SES. The sample naming scheme and SES floor plan showing outlet locations labeled by outlet ID are provided in Appendix B and C, respectively.

³The U.S. EPA (2006) recommends against sampling during holidays or periods of time that the school is not in regular use in order to avoid collecting samples that have non-representative high levels of lead.
⁴Some outlets are used infrequently and had likely been sitting for longer than 8-12 h. We considered this to be in keeping with the goals of the EPA guidance in that our samples are representative of what a student might encounter at that particular outlet on a given day.
⁵School samples are smaller than the 1-L sample collected by public water suppliers for compliance with the Lead and Copper Rule. A smaller sample is more effective at identifying the sources of lead at an outlet because lead sample is also more representative of water per serving consumed by a child. (EPA 2006)

</tr>
</tbody>
</table>

Sample Preparation and Lead Analysis

After collection, samples were placed in a cooler and within 48 hours were acidified to 0.5% (1.25 mL trace-metal grade HNO₃) for preservation. After 16 h or more, sample turbidity was verified to be <1 NTU and acidity pH<2. Samples were analyzed for lead using inductively coupled plasma mass spectrometry, manufacturer-recommended conditions, and conventional quality control and quality assurance methods. Lead concentrations are reported to the nearest part-per-billion (ppb, i.e., μg-Pb/L-water) for samples at/above the limit of quantification (LOQ, 1 ppb); as <1 ppb for samples with detectable lead below the LOQ; and as non-detect (n.d.) for samples with lead levels below the limit of detection (0.1 ppb). A health-based prioritization of outlet remediation (highest, high, or moderate priority) is made based on the measured lead levels in FD samples and the potential use of the outlet for direct consumption. Lead levels are evaluated relative to two voluntary standards: the administrative (not health-based) EPA action level for lead of 15-ppb and the American Academy of Pediatrics health-based safety standard for school water fountains of 1 ppb. The AAP recommendation is based on the fact that children use water fountains for direct consumption; in this report, we extend this recommendation other outlet types that might also be readily used for direct consumption by children, including bottle filling stations, classroom sinks, kitchen sinks/sprayers, and bathroom sinks.

RESULTS & DISCUSSION

Lead Level Summary

Water from 28 outlets was sampled, including collecting one FD and one FL sample from each outlet. FD samples are used to evaluate lead exposures, while FL samples are used to evaluate the potential source of any lead found. Complete sample data are provided in Appendix C. Summary results for FD samples are shown in Figure 2. Most of the 28 outlets sampled (75%) produced FD samples that were at 1 ppb or lower and, therefore, meet the American Academy of Pediatrics (AAP) recommended safety level for school water fountains. No samples exceeded the EPA action level. Seven outlets (all sinks) produced FD samples at 2 ppb or higher (range 2-14 ppb), exceeding the AAP recommendation (Figure 3). The potential health concerns posed, and therefore, the prioritization of outlets for remedial action, depend on the measured lead concentration and the potential use of the outlet for direct consumption.

---

6 Reliability was ensured by use of a 7-point calibration ($r^2>0.999$) with use of internal standards; analysis of field and calibration blank samples; analysis in triplicate (±10%); and Pb recovery for a National Institutes of Standards and Technology certified reference material (±10%) after every 10 samples.
Figure 2. Summary of lead levels in Shoreham Elementary School FD samples (total outlets = 28). Numbers represent the number of outlets producing FD samples in each lead concentration category. No FD samples exceeded the EPA action level.

Figure 3. Shoreham Elementary School outlets that exceeded the American Academy of Pediatrics recommended safety level of 1 ppb.

Seven sinks produced FD lead levels (2-14 ppb) that were below the EPA action level, but exceeded the AAP recommendation:

- a kitchen sprayer and sink (3 ppb, OR04; 2 ppb, OR05)
- three classroom sinks (GN01, 14 ppb (Room 1); GN03, 2 ppb (Room 2); and PK02, 3 ppb (Kindergarten))
- an office/library sink (YW01, 5 ppb)
- a utility sink located in a custodial closet (GN09, 8 ppb).

We consider the kitchen sprayer/sinks as a highest priority for remediation because they are likely to
be used for food preparation. Although SES children and staff are advised against drinking from sinks [19], these outlets are available and often convenient for use by children and staff; we did not note any signage instructing against their use for direct consumption. For these reasons, we include the classroom and office sinks as a high priority for remediation. The utility sink is located within a custodial closet and is highly unlikely to be used for consumption, so we categorized this as a low priority for remediation. Priority outlets for remediation are summarized and appropriate remedial actions are discussed below in the Summary & Recommendations section.

Source of Lead in Water

FL samples had lower lead levels as compared to their associated FD sample, which suggests that the predominant source of the lead in the FD samples is the outlet fixtures or immediate connections (e.g., solder) rather than incoming water or pipes within the school. Moreover, all FL samples were either non-detect for lead or lead was present only at trace levels (e.g., <1 ppb), which suggests that flushing may serve as an effective temporary measure for the priority outlets.

SUMMARY & RECOMMENDATIONS

Most of the 28 outlets (25 outlets, 89%) produced FD samples with detectable lead, but nearly three-quarters of these were at trace levels or lower (i.e., <1 ppb) and are not considered to be a safety concern. No samples exceeded the EPA action level. Seven sinks produced FD samples at 2 ppb or higher (range 2-14 ppb), exceeding the health-based 1-ppb AAP safety recommendation. A summary of outlets prioritized for remediation is shown in Table 2.

Table 2. Summary of Shoreham Elementary School outlets that exceeded the AAP recommended safety level, with suggested prioritization for remediation based on lead level and likelihood and frequency of use for consumption.

Remedial actions include permanent (preferred) and temporary measures; appropriate actions depend on the source of lead in the water. At SES, the results suggest that the source of lead is overwhelmingly the fixtures or their immediate connections and not more distal pipes or the incoming water supply, which simplifies potential remediation approaches.

We recommend that SES pursue the following permanent remediation approach for priority outlets (Table 2, Figure 3):
1) replace existing outlet fixtures with “lead-free” fixtures/solder or remove the outlets entirely
2) if replaced, verify remediation efficacy via follow-up lead testing following replacement
Until priority outlets are permanently remediated, we suggest that SES pursue the following temporary approaches:

1) disconnect water supply to priority sinks in locations where water is not needed for non-consumption uses

2) for priority sinks in locations where water is needed for non-consumption uses,
   a. establish school-wide policies for water consumption from outlets by outlet type (e.g., “only drink from water fountains and bottle fillers,” or “do not drink from sinks” or “flush prior to use for consumption), rather than location-specific policies
   b. complement school-wide policy with age-appropriate signage at each priority outlet instructing on the school-wide policy and with educational outreach regarding the policy and its rationale

Finally, we recommend that SES communicate the findings of this work and remediation updates with the school community, as well as post this report and remediation updates in a readily accessible location (e.g., school website). A draft letter describing the results for a general audience is provided as Appendix E.

ACKNOWLEDGEMENTS
The authors are grateful to Mr. Eric Warren, ACDS Facilities Manager, and Mr. Bruce MacIntire, ACSD Director of Facilities, for providing access to and technical and historical information about SES, and for assisting in communicating with the school community about the project. We would like to thank Dr. Peter Burrows, ACSD Superintendent for his support of the work. Finally, we gratefully acknowledge the assistance of Jody Smith, Senior Instrument Technician at Middlebury College, for instrument support, maintenance, and student training. This project was funded by the Dept. of Chemistry and Biochemistry and the Senior Work Fund at Middlebury College.

Appendix A – Communication with School Community Prior to Sampling

The following letter was drafted for SES to share with the school community prior to commencing sampling.

Dear Parents,

This winter, Shoreham Elementary School (SES) will partner with students and faculty researchers from Middlebury College to test all the sources of drinking water at SES for lead. SES is pursuing this testing, because Middlebury College is incorporating this testing into one of its courses, and the drinking water testing will be conducted at no cost to the school.

**Why is it important to screen to test the school’s drinking water for lead?** Although most lead exposure occurs when people eat paint chips and inhale dust, the EPA estimates that up to 20% of lead exposure may come from drinking water. Even though the public water supply to the school meets EPA’s lead standards, lead can still get into a school’s drinking water. As water moves through a school’s plumbing system, lead can leach into the drinking water from plumbing materials and fixtures that contain lead. Testing is the best way to know if there are elevated levels of lead in the school’s drinking water.

**How will samples be taken?** Student researchers will follow standard EPA methods and guidelines to take the samples from any taps supplying water that may be consumed including drinking fountains and bathroom, kitchen, and classroom sinks. Samples will be analyzed at Middlebury College.

**How long will it take to get the results?** Laboratory results should be available within 2-4 weeks after samples are collected. The results will be reviewed by the school to determine if any follow-up actions are needed, although none are anticipated based on the previous testing. Results will be shared with parents, faculty, and staff within two weeks after the results are received by the school.

**What will happen if there is lead in the drinking water at the school?** Fixtures that show lead levels at or above the action level of 15 parts per billion (ppb) will require follow-up sampling to pinpoint the source of the lead (pipes or fixtures). If lead levels are at or above 15 ppb, the school is committed to fixing the problem using a combination of easy fixes including:

- Routine practices (clean debris from screens, flush holding tanks, place signage).
- Permanent measures (install filtration systems, replace piping, replace water fixtures).

**Where can I get more information?** For more information regarding the testing project or sampling results:

- Call Bruce MacIntire at 802-382-1500

**For information about the health effects of lead:**
- Call the Health Department at 800-439-8550
- Visit [http://healthvermont.gov/drinking-water/lead](http://healthvermont.gov/drinking-water/lead)

**To request a drinking water test kit:**
- Call the Health Department Laboratory at 802-338-4736 or 800-660-9997

Sincerely,

Dr. Peter Burrows
Superintendent ACSD
Appendix B - Sample-Naming Scheme

Samples collected at SES were assigned unique sample IDs as presented below. The IDs are composed of the school code, sampling date, flow path identification, outlet ID, and the type of sample.

- School code
- Outlet ID = water flow path code (color) + outlet number, indicating location along flow path
- Date of sample collection
- Sample type (FD = first draw; FL = flush) + replicate number

SES_01132018_BL01_FD1
### Appendix D – Complete Lead Concentration Results for SES

Samples were collected as described in the Methods; sample names are as described and located in Appendix B and C, respectively. Lead concentrations are reported in parts-per-billion (ppb, i.e., μg-Pb/L-water) for samples at/above the limit of quantification (LOQ, 1 ppb); as <1 ppb for samples with detectable lead below the LOQ; and as non-detect (n.d.) for samples with lead levels below the limit of detection (i.e., <0.1 ppb). No samples exceeded the EPA action level. Samples that exceeded the AAP (but not the EPA) recommended safety level are shown in blue.

Appendix E – Sample Letter to the SES Community Regarding Study Results

We provide here a sample letter for sharing the study results with the school community.

Dear Parents,

As we shared this past spring, Shoreham Elementary School (SES) partnered with students and faculty researchers from Middlebury College to test all the sources of drinking water at SES for lead, including water from water fountains and sinks -- a total of 28 outlets.

**Why is it important to screen to test the school’s drinking water for lead?**

Although most lead exposure occurs when people eat paint chips and inhale dust, the U.S. Environmental Protection Agency (EPA) estimates that up to 20% of lead exposure may come from drinking water. Even though the public water supply to the school meets EPA’s lead standards, lead can still get into a school’s drinking water. As water moves through a school’s plumbing system, lead can leach into the drinking water from plumbing materials and fixtures that contain lead. Testing is the best way to know if there are elevated levels of lead in the school’s drinking water.

**What were the results of the study?**

Most of the 28 outlets sampled (75%) were at 1 ppb or lower and, therefore, met the American Academy of Pediatrics (AAP) recommended safety level for school water fountains. Seven sinks, including two in the kitchen, four in classrooms or offices, and a utility sink in a custodial closet exceeded the AAP recommendation, with lead concentrations ranging from 2 to 14 ppb. Researchers categorized the kitchen sinks as *highest priority* for remediation due to their potential use for direct consumption and use in food preparation. The classroom or office sinks were categorized as a *high priority* for remediation due to their potential use for consumption, and the utility sink was considered a *low priority* for remediation because it is unlikely to be used for consumption. Testing suggests that the predominant source of lead is the fixtures or their immediate connections, rather than more distal pipes or the incoming water supply.

**What comes next?**

We have accepted the researchers’ recommendations that we:

1. replace older fixtures and those with demonstrated exceedances – especially those used for consumption – with newer Pb-free fixtures and Pb-free solder – or remove the outlets entirely.
2. Verify remediation efficacy via follow-up lead testing following replacement

[INSERT LANGUAGE ON TIMELINE FOR RESPONSE/IMPLEMENTATION AND OF FOLLOWUP AFTER CHANGES HAVE BEEN MADE/IMPLEMENTED]

**Where can I get more information?**

For more information regarding the testing project or sampling results:
- Call Bruce MacIntire at 802-382-1500
- Access the full report at [INSERT URL FOR ACCESSING THE FULL REPORT]

For information about the health effects of lead:
- Call the Health Department at 800-439-8550
- Visit [http://healthvermont.gov/drinking-water/lead](http://healthvermont.gov/drinking-water/lead)

To request a drinking water test kit:
- Call the Health Department Laboratory at 802-338-4736 or 800-660-9997
